Accepted 3rd September 2016

Abstract: In this study, it is aimed to reduce the variability of parameters in the liquid level system controlled by PID controller for a laboratory scale device. An integrated methodology consisting of experimental design and feedback PID (proportional-integral-derivative) controller was proposed to optimize and control the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system. The optimal valve opening levels that minimizes the average of the offset value (μ), variance (s^2) and the first time to reach the set value (t) were determined as 40%, 5%, 50% and 80%, respectively, using TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution)-based Taguchi method by Minitab®. A quite successful control was established in the verification test which performed with specified levels of optimal valve opening. Recovery rates in the control performance before and after optimizing the parameter were calculated as 9.53% in the deviation from the average value in the offset values, 29.37% in the variability in the offset value and 11.27% in the time to reach the set value. MATLAB/Simulink was used to simulate the liquid level system.

Keywords: Laboratory Scale Liquid Level System, TOPSIS based Taguchi Parameter Design, PID Controller and Performance Improvement

1. Introduction

Liquid level loops are frequently encountered in many process industries such as waste water management systems and petrochemical processes [1] – [4]. Especially in the petroleum industry, liquid level is a crucial parameter for production at oil wells [5]. In recent years, many researchers studied on controlling of liquid level systems [6]. Sbarbaro and Ortega (2007) proposed a new approach to control the multi-tanks systems [7]; Almutairi et al. (2007) proposed several sliding mode control diagrams for the coupled tanks [8]. Lee and Shin (2009) applied constrained control to liquid level system using conventional PI (proportional-integral) controller [1]. Zhang et al. (2011) modelled and controlled the liquid level in a coke fractionation tower using non-linear based predictive control [9]. Noel and Pandian (2014) proposed an integrated methodology including artificial neural network based reinforcement learning approach for controlling of a nonlinear liquid level system [10]. Sadeghi et al. (2014) designed a method based on parallel distributed compensation via fuzzy Takagi-Sugeno model for a liquid level system [11]. Singh et al. (2014) reduced flow rate fluctuation for tank in series with PI controller [12]. Zhang et al. (2014) offered PI controller based on predictive functional control for liquid level in a coke fractionation tower [9], [13]. In the literature, many studies contain process optimization and control applications have proposed for various industrial areas. Some of these studies are as follows; Tao et al. (2014) applied predictive control based PID design with genetic algorithm for chamber

pressure in coke furnace [13], Zhang et al performed model predictive control optimization based PID control for temperature in an industrial surfactant reactor [14], Zhang and Yang (2014) developed an incremental-PID-controlled particle swarm optimization algorithm for EGG-data-based estimation of operator functional state [15]. Sahu et al. (2015) proposed teaching-learning based optimization algorithm based fuzzy-PID controller for automatic generation control of multi-area power system [16], Gizi et al. (2015) formulated an integrated approach programmable logic controller-fuzzy PID methodology to determine optimal PID parameter in automatic voltage regulator [17].

Many difficulties are experienced in liquid level control systems owing to the variability in the parameters and flow resistance [3]. Parameter variations that should be controlled can be originated from pumps, agitators or the natural causes [3]. In this study, it is aimed to reduce the variability of parameters in the laboratory scale liquid level system controlled by PID controller. Purpose of reduction of parameters' variability and noise effect with the methodology including multi-criteria decision making (MCDM) based Design of Experiment (DoE) for finding optimal valve opening levels and process control performance improvement. Moreover, the improvement rate was also specified by finding valves' opening levels to optimize the process control performance. Giving a positive and negative effect on the system, system performance was evaluated after the parameter optimization. Matlab/Simulink® was used to simulate the laboratory scale liquid level system (LSLLS).

2. Proposed Materials & Methodology

2.1. Materials

Liquid level control techniques can be applied experimentally by a LSLLS built up from standard industrial parts (Figure 1). It is

possible to observe the control techniques used in the industry. P, PI and PID control methods can be examined experimentally with LSLLS. The reaction of the control data can be measured with changing operation conditions. Pressure tracking can be done in four different points via an analogue type industrial manometer. Liquid level in the plexi tank can be measured by HK Instruments DPT-R8 differential pressure sensor. Accuracy of DPT is ± 1.5 or ± 6 Pa under 250 Pa. Control data can be recorded by the Pangu KT104 digital data recorder. It can record and show process data graphically and visually. Width of the cylindrical liquid tank of LSLLS is 75 cm and height of the tank is 200 cm. Experimental set has a pneumatic proportional valve consist of Young Tech Instruments YT100 electrical junction box, positioner, PVD T-PA40 pneumatic actuator and an 1.0 inch inner diameter ball valve.

Valve no. 1 breaks the water come from the water pump, Valve no. 2 is the by-pass valve connected to pneumatic proportional valve, Valve no. 3 is located at the plexi tank water inlet and Valve no. 4, drain valve, is located at the plexi tank water outlet. The block diagram of the LSLLS was given in Figure 2.

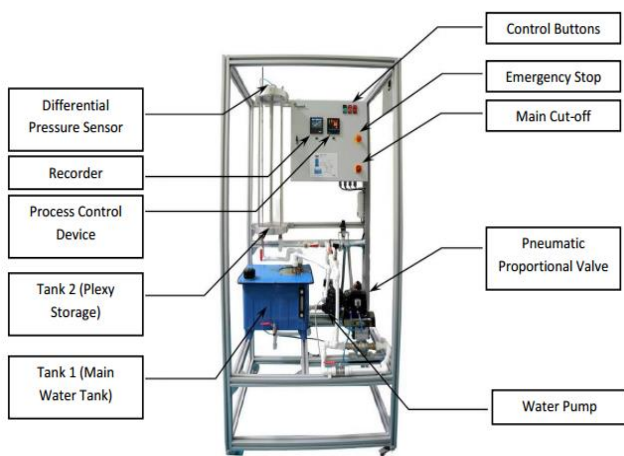

Figure 1. Laboratory scale liquid level system

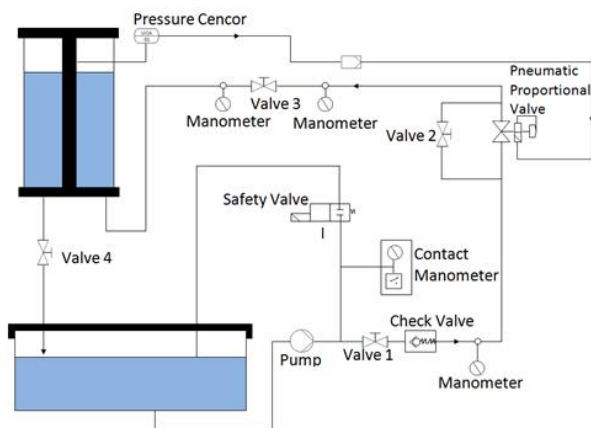

Figure 2. Block diagram of laboratory scale liquid level system

2.2. Proposed Methodology

Proposed methodology contains two stages including parameter optimization and control. In first stage, optimal valve opening levels were determined to minimize the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system using TOPSIS based Taguchi methodology. In second stage,

process control performance of the system was monitored via optimum valve opening; dynamic behavior of LSLLS with positive and negative step change was examined, closed-loop block diagram was established by Matlab/Simulink® and process control performance improvement rate was calculated between former and optimal valve opening levels. Flow diagram (including 10 flow steps used in the study in process control performance optimization of LSLLS) is given in Figure 3.

2.3. Determining Performance Criteria for The Success of Process Control

Three performance criteria for the successful process control were defined as deviation from the average value in the offset value, variability in the offset value and the time to reach the set value. Target values and weights of performance criteria were given in Table 1.

PARAMETER OPTIMIZATION	PROCESS CONTROL
STEP 1 • Determine LLS optimization and control objectives	STEP 6 • Calculation the PID parameters with statistical model definition
STEP 2 • Determine performance criteria for the success of process control	STEP 7 • Development of a closed loop feedback block diagram using MATLAB Simulink®
STEP 3 • Determination of parameters and their levels	STEP 8 • Obtaining the transfer function of LLS
STEP 4 • Determine optimization and control methodology	STEP 9 • Examination of the dynamic behaviour of LLS giving positive and negative step change
STEP 5 • Implement of Taguchi design with TOPSIS • Obtain experiment results using PID controller • Calculation of offset mean, offset variation and time to reach the setpoint • Optimization using TOPSIS based Taguchi design using MINITAB® • Validation experiment	STEP 10 • Calculation of process control performance improvement between former and optimal conditions

Figure 3. Proposed process optimization and control methodology

Offset value is steady-state difference between the set point which is 60 cm with the actual point obtained in liquid level control system. The average of these values was defined as mean of the offset values, the variance of these values was defined as variance of the offset values, respectively. Time to reach the set point was described as the first time to reach 60 cm. 8th, 7th and 4th values were designated to mean of the offset values, the variance of these values and time to reach the set point, respectively. All criteria representing process control performance are required to be minimized.

2.4. Determining Levels of Performance Criteria

Each globe valve which has ½ inch inner diameter, effect on performance criteria has three levels and their description was shown in Table 2. Tank no. 1 filled with city water was used as fluid in the system. Process parameters, valve opening levels, were set before each experiment's implementation. The system was run for twenty minutes. In all experiments, an industrial type PID controller (Ordel AC991) was utilized to control the liquid level at Tank no. 2. An industrial differential pressure transmitter which can measure pressure difference up to 7 kPa was used to effectively measure the fluid level. Measurements were sent to PID controller as electrical signals. PID controller calculates valve opening position of pneumatic proportional valve, required to control system. Experimental data were collected by industrial data-logger during the system run.

2.5. TOPSIS Based Taguchi Design and PID Controller Algorithm

TOPSIS based Taguchi Method is a design of experiment technique takes only linear effects into account was used to determine optimal valve opening levels. The details of this

Table 1. Performance Criteria and Their Weights

Performance Criteria	Symbol	Description	Target values	Weights	Normalized Weight
1	μ	mean of the offset values (cm)	Smaller is better	8	0.421
2	s^2	variance of the offset values (cm ²)	Smaller is better	7	0.368
3	t	time to reach the set point (s)	Smaller is better	4	0.211
N/A			Total	19	1.0

methodology were expressed in Şimşek et al. [18]. PID controller algorithm which is dominant type in feedback controller finds wide application coverage in industry [19]. Macro-scaled continuous process contains between five hundred with five thousand feedback controller for various process variables [19]. 97% of the controllers used are some forms of PID controller. Transfer function of PID control algorithm parallel form is given in equation (1) [19];

$$\frac{P'(s)}{E(s)} = K_C \left(1 + \frac{1}{\tau_I s} + \tau_D s \right) \quad (1)$$

Proportional gain, integral gain, derivative gain are tuning parameters which are symbolized as K_c , τ_I and τ_D , respectively [19]. In this study, Matlab PID tuner was used to determine the process control parameters.

2.6. Development of a Theoretical Model for Simulink

Several model approaches can be used for process control applications. Theoretical models which are obtained by process physics and chemistry can be used in industry. Development of theoretical models may not be a practical way when model requires process variables and unknown parameters (i.e. physical and chemical properties) including many equations. Development of an empirical model from experimental data directly can be an alternative approach [19].

3. Results and Discussion

3.1. Results

In this study, a Taguchi's (3^4) orthogonal array was used to implement the experiments and results are given in Table 3 [20]. In Table 3, columns 2–5 represent the four control factors and their levels. Findings relevant to the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value in this liquid level system were given in columns 6–8. Table 3 also contains PID tuning parameters such as proportional gain, integral gain, derivative gain which is shown in columns 9–11.

3.2. TOPSIS Based Taguchi Design

In this study a Taguchi orthogonal array ($L_9;3^4$) was selected to implement the experiments. Signal to noise ratios (S/N) were calculated for the smaller the better type responses and given in columns 2–4. Let n_{ij} be the S/N for the response j of experiment i and let y_{ijk} be the experiment result for the response j of experiment i , in the k^{th} replication; n is the total number of replications [18], [21]. The calculation of the S/N ratio can then be determined as [22];

$$n_{ij} = -\log K_C \left(\frac{1}{n} \sum_{k=1}^n y_{ijk}^2 \right) \quad (2)$$

In Table 4, columns 5–7 are shown as decision matrix which is essential step of the TOPSIS method [26]. The positive ideal solution (S_i^+), and negative ideal solutions (S_i^-) and C_i^* ($i=1 \dots 9$), are the surrogate responses for the multi-response minimization problem [18].

The average responses by factor levels can be designated by utilizing the additive property [18], [23]. Their associated factor effect plots are given in Figure 4 [18]. Since the effect values are smaller-the-better, normalization methods caused the final parameter design of $A_2 B_2 C_3 D_2$ which is given in Table 5.

3.3. Validation of experiment and PID tuning parameters' calculation

In order to confirm the optimum valve opening levels achieved using the TOPSIS based Taguchi method, an experimental study was implemented to check whether the deviation from the average value in the offset value, variability in the offset value and the time to reach the set value could really be minimized by the proposed optimum valve opening levels. The confirmation study improvement for mean of the offset values, variance of the offset values and time to reach the results which are given in Table 6 demonstrated that proposed results satisfies the expected set point. PID tuning parameters of validation experiments were calculated as 0.57 for proportional gain, 4.54 for integral gain, and 13.64 for derivative gain using well-known statistical model definition techniques.

3.4. Development of a Closed-Loop Feedback Block Diagram Using Matlab/Simulink®

Transfer function of a laboratory scale liquid level system can be modeled utilizing orifice and mass balance equation to describe the dynamics of chemical process given in Seborget. al. [19]. A block diagram representing the laboratory scale liquid level system was obtained by Matlab/Simulink® tool can be seen in Figure 5. PID controller tuning parameters were received as 0.57 for proportional gain, 4.54 for integral gain, 13.64 for derivative gain. System response against step change can be seen in Figure 6.

4. Conclusion

This research offered an integrated process optimization which is MCDM based experimental design and process control methodology to improve process control performance in a laboratory scale liquid level system. Following the TOPSIS based Taguchi procedure, process control performance of the system was monitored using optimal valve opening levels.
